

Voice path, PCM system, Line code

✓ PCM ~ Pulse Code Modulation

- › Sampling
- › Quantizing
 - Linear
 - Non-linear
- › Quantizing error

✓ TDM- time division multiple access

- › PCM-frame structure, CRC4 -multi-frame
- › PCM 30, PCM 120, PCM 480, PCM 1920 (see also course s38.118)
- › PCM-line code

Summary of course scope

Requirements for the Voice path and the Switching Fabric

- ✓ **The Switching Fabric must understand the bits, the timeslots and the frames in the same way as the transmission systems that carry the bits**
 - › The Fabric and the transmission systems must be synchronized
- ✓ **Voice must be coded efficiently (what is efficient changes over time)**
- ✓ **CRC -multi-frame must enable transparent transmission (= any octet values can be sent over the network freely)**
- ✓ **An exchange must supervise voice connections:**
 - › calls shall/should not be offered to faulty connections
 - › calls must sometimes be cleared from faulty connections
 - › detected faulty connections must be reported to far end if possible

Sampling

- ✓ **Nyquist theorem**
 - › If an analogue signal with limited spectrum is sampled regularly with a frequency of at least twice as high as the highest frequency component, the samples carry all the information in the original signal. The original signal can be reconstructed using a low pass filter.
- ✓ **In voice transmission, the spectrum carried is specified to be 300 - 3400 Hz, resulting in a minimum sampling rate of 6,8 kHz.**
- ✓ **In practice, since the width of the transmission channel in an analogue system is 4kHz, in a digital system a sampling rate of 8 kHz (8000 samples/s) is used.**

Digital voice transmission

- ✓ The voice path includes a microphone, A/D-converter, D/A-converter and a loudspeaker.
- ✓ In practice, the analogue signal needs to be filtered before the conversion

Pulse Code Modulation - PCM

- ✓ In PCM, analogue voice is digitized and thus it can be carried by digital transmission systems and switched in digital switching fabrics.
- ✓ PCM was invented in 1937 but the first real implementations became possible only using transistor technology during 1960's. This is also one of the origins of Nokia Electronics (1968) and Nokia Telecommunications.
- ✓ PCM conversion has four steps:
 - > filtering
 - > sampling
 - > quantizing
 - > coding

Sampling of the analogue signal

- ✓ Sampling of the analogue signal is done with a frequency of 8 kHz, i.e. with an inter-sample interval of 125 μ s.
- ✓ The result is a PAM -signal

Telecommunications Switching Technology I

3 - 7

Pulse Amplitude Modulation PAM

- ✓ Sampling produces a time discrete PAM signal reflecting the amplitude of the analogue signal.
- ✓ PAM-signal is quantized producing PCM-code.

Telecommunications Switching Technology I

3 - 8

Quantizing results in approximation of the samples

- ✓ Real valued amplitude figures are replaced by discrete integer values.
- ✓ Quantizing should result in values that appear in the signal with equal probability.

Quantizing distortion

- ✓ Quantizing produces distortion, that is called quantizing distortion.
- ✓ Quantizing distortion is made by the replacement of real values by their integer approximates and at maximum can reach $\frac{1}{2}$ quantizing interval.
- ✓ In linear quantizing the signal to distortion ratio is

$$\boxed{S/D=6n+1,8 \text{ dB} \quad n=\text{word length}}$$

Linear vs. non-linear

- ✓ The result of quantizing should use signal values with equal probability.
- ✓ This results in minimization of distortion, because a larger number of discrete signal values falls into the most typical analogue signal value area.
- ✓ In a voice signal, small analogue values appear with higher probability than larger values.

--> non-linear quantizing

Non-linearity

- ✓ Non-linear conversion can be implemented in two ways:
 - › using non-linear quantizing
 - › using compression before linear quantizing is applied
- ✓ Non-linear quantizing can be implemented e.g. using a network of resistors, compression requires a non-linear amplifier.
- ✓ Irrespective of the method of implementation, the non-linear quantizing follows a conversion function giving the mapping of analogue signal values to integers.
 - › In Europe (ETSI) A-function
 - › In USA (ANSI) μ -function

PCM-coding and quantizing

✓ According to ETSI specification, voice coding uses 8 bits per sample.

- › bit-1 gives the polarity of the signal
- › bits 2-4 give the segment of the non-linear quantizing
- › bits 5-8 give the value of the discrete signal inside the segment

✓ Non-linearity follows the so called A-law

$$\left(\frac{A|x|}{1+\ln(A)} \right) \left| 0 \leq |x| \leq \frac{1}{A} \right.$$

$$\left(\frac{1+\ln(A|x|)}{1+\ln(A)} \right) \left| \frac{1}{A} \leq |x| \leq 1 \right.$$

The value of A is 87,6.

Quantizing according to the A-law

Quantizing inside a Segment

- ✓ In a segment quantizing is linear

Linear vs non-linear quantizing

- ✓ Linear and non-linear quantizing can be compared using the gain in signal resolution by non-linearity.
- ✓ Non-linear quantizing emphasizes small signal values, for which a gain in resolution of 24 dB is achieved.

$$G_{dB} = 20 \log V_{in} / V_{comp}$$

PCM-hierarchy

- ✓ **PCM-hierarchy is created by overlapping time division multiplexed signal connections bit by bit. Bits become shorter.**
- ✓ **The basic speed in the hierarchy is the bitrate of a single voice channel**

$$S=8000\text{Hz} * 8\text{bit} = 64\text{kbit/s}$$

- ✓ **The following voice channel groups are defined**
 - › 30 voice channels
 - › 120 voice channels
 - › 480 voice channels
 - › 1920 voice channels

PCM 30 (E1)

- ✓ **The most common information switching and transmission format in the telecommunication network is PCM 30.**
- ✓ **PCM 30 contains:**
 - › 1 synchronization and management channel
 - › 1 signaling channel
 - › 30 voice channel
- ✓ **A channel is a time slot in the PCM-frame (125µs), created by TD multiplexing.**
- ✓ **PCM 30 system carries 32 time slots, each 64kbit/s. This gives a total bit rate of 2048kbit/s.**

PCM 30 frame

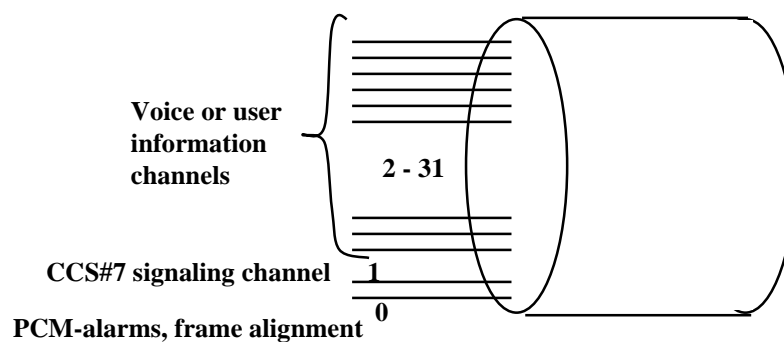

✓ PCM 30 -frame contains 32 time slots

- › time slot 0 is dedicated for synchronization and management information
- › Time slot 16 is assigned for signaling information (CAS)
- › Time slots 1-15 and 17-32 are voice or user information channels

✓ Even and odd frame structures differ

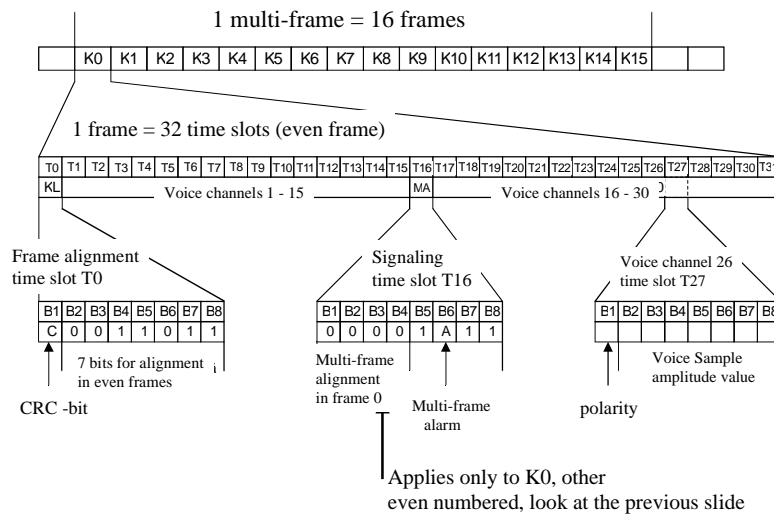

- › In even numbered frames time slot 0 carries the frame alignment signal (C0 01 10 11). C is the CRC-bit (cyclic redundancy check) for ensuring the frame alignment recovery in case someone is sending X0 01 10 11 on a user information channel.
- › Time slot 0 in odd frames carries alarm information. To avoid wrong frame alignment, the second bit in tsl 0 is set to the constant value of 1.

The use of PCM time slots in the Finnish CCS#7 network

Nowadays, tsl 16 is used for voice!

CRC-4 calculation ensures, that the frame alignment function can not lock into a user signal of (x0011011)

		Frame_nr	t0/1	t0/2	Tsl-0/bit x	
CRC-4 multi-frame	I-half	0	C1	0	0	1
		1	0	1	A	1
		2	C2	0	0	0
		3	0	1	A	1
		4	C3	0	0	0
		5	1	1	A	1
		6	C4	0	0	0
	7	0	1	A	1	
	II-half	8	C1	0	0	0
		9	1	1	A	1
		10	C2	0	0	0
		11	1	1	A	1
		12	C3	0	0	0
		13	E	1	A	1
		14	C4	0	0	0
15		E	1	A	1	

C1...C4 - CRC4 -bits
 E - CRC4-error bits
 001011 - CRC4 -multi-frame alignment
 A - far-end alarm (t0-frame alignment lost)

E1 Frame alignment algorithm/ G.706

Higher levels in the hierarchy

✓ PCM multiples

- › PCM 30 (E1) 2,048Mbit/s
- › PCM 120 (E2) 8,448 Mbit/s
- › PCM 480 (E3) 34,368 Mbit/s
- › PCM 1920 (E4) 139,264 Mbit/s

- ✓ Multiples are formed by multiplexing frames from four lower level connections into new higher order frames. Management overhead info is added into the higher order frame.

Line code in the PCM system

- ✓ PCM-system uses bipolar transmission.

- ✓ Binary one is transmitted only during 50% of the cycle time.

- › There is no direct current that would need to be eliminated
- › Power spectrum is concentrated around $\frac{1}{2}$ bit rate

- ✓ Two alternative line codes are used in the PCM system:

- › AMI - Alternate Mark Inversion
- › HDB3 - High Density Binary 3

Alternate Mark Inversion - AMI

✓ In the AMI-code

- › Binary one changes polarity at each occurrence
- › Binary zero is no signal on the line

✓ Weakness is in losing bit sync in case of long series of zeroes.

High Density Binary 3 - HDB3

✓ In HDB3 code

- › Binary one changes polarity as in the AMI-code
- › Binary zero
 - First zero is replaced by "one" if in the previous group, an inversion was used
 - Second and third zeroes are no signal
 - The fourth consecutive zero raises an inversion - I.e. violation of the code, I.e. a pulse with the same polarity as the previous one or "one" is transmitted
